In the claims:

1. (currently amended) A method for determining the thickness of material by penetrating the material, in particular a method for measuring the thickness of walls, ceilings and floors, with which a measurement signal (28) in the gigahertz frequency range emitted using a <u>single</u> high-frequency transmitter (24) penetrates the material (10) to be investigated at least once and is detected by a <u>single</u> high-frequency receiver (38),

wherein the thickness (d) of the material (10) is measured via at least two transit-time measurements of the measurement signal performed atfor various positions (20, 22) of the <u>single</u> high-frequency transmitter (24) and/orand the single high-frequency receiver (34) operated in a same hand-held device.

- 2. (original) The method as recited in Claim 1, wherein the high-frequency transmitter (24) and the high-frequency receiver (38) are operated on a first surface (14) of the material (10), and the measurement signal (28) from the high-frequency transmitter (24) is reflected back to the high-frequency receiver (38) by a reflector means (18).
- (original) The method as recited in Claim 2,
 wherein, the reflector means (18) includes a transponder (40,140, 240, 340).

Claim 4 cancelled.

- 5. (currently amended) The method as recited in Claim 41, wherein the measuring device (12) is moved over a surface (14) of the material to record the at least two transit-time measurements.
- 6. (original) The method as recited in Claim 5, wherein, the displacement path (s) of the measuring device (12) is detected.
- 7. (original) The method as recited in Claim 1, wherein the measurement signal (28) is generated in the gigahertz frequency range using a pulsed-radar method and is launched into the material (10).
- (previously presented) The method as recited in Claim 1, wherein one or more measurement frequency/frequencies (28) are used in an interval of 1000 MHz to 5000 MHz, and preferably in an interval of 1500 MHz to 3500 MHz
- 9. (previously presented) A device system for carrying out the method as recited in Claim 1, wherein the device includes at least one high-frequency measuring device (12) capable of being placed on a surface (14) of a material (10), with at least one high-frequency transmitter (24) and a high-frequency receiver (38), and a transponder (40, 140, 240, 340) capable of being moved relative to this high-frequency measuring device.

- 10. (previously presented) The system as recited in Claim 9, wherein the at least one high-frequency measuring device (12) includes a position-detection system (50, 52) for recording a path (s).
- 11. (new) A method for determining the thickness of material by penetrating the material, in particular a method for measuring the thickness of walls, ceilings and floors, with which a measurement signal (28) in the gigahertz frequency range emitted using a single high-frequency transmitter (24) penetrates the material (10) to be investigated at least once and is detected by a single high-frequency receiver (38), wherein the thickness (d) of the material (10) is measured via at least two transit-time measurements of the measurement signal performed for various positions (20, 22) of the single high-frequency transmitter (24) and the single high-frequency receiver (38) are operated on a first surface (14) of the material (10), and the measurement signal (28) from the single high-frequency transmitter (24) is reflected back to the single high-frequency receiver (38) by a transponder (18) located on a second surface (16) of the material (10).
